Issued 1984-08
Revised 2009-12

Superseding J1459 SEP2001

V-Ribbed Belts and Pulleys

RATIONALE

This document has been revised to update the pulley cross sections, specifically the definition of pulley flanges to improve robustness against belt misinstallation.

1. SCOPE

This SAE Standard covers the dimensioning technique, tolerances, and methods of measurement of V-ribbed belts and mating pulleys for use on automotive accessory drives.

2. REFERENCES

There are no referenced publications specified herein.

3. V-RIBBED BELTS

Although several v-ribbed cross sections are available, this document shall be confined to "PK" (K) section belts which are used in automotive applications, including trucks at least up to Class 3. Belts shall conform to Figure 1.

4. PULLEYS MATING WITH V-RIBBED BELTS

It is the intention of this document to relate the belt profile to the pulley profile using the variables associated with the 2.50 mm ball used in measuring pulley diameters. Pulleys shall conform to Figures 2, 3 and 4. Figure 2 shows a split pulley section, Figure 3 a folded pulley section – both preferred constructions. Figure 4 shows an optional folded pulley section.

4.1 Pulley Diameter Definitions

The diameter over balls (DoB) is the only diameter measured on a pulley in the groove/flange area. There are other diameters used that are calculated from this value. The ball diameter is defined as $2.500 \text{ mm} \pm 0.010 \text{ mm}$. See Tables 1A and 1B.

SAE Technical Standards Board Rules provide that: "This report is published by SAE to advance the state of technical and engineering sciences. The use of this report is entirely voluntary, and its applicability and suitability for any particular use, including any patent infringement arising therefrom, is the sole responsibility of the user."

SAE reviews each technical report at least every five years at which time it may be reaffirmed, revised, or cancelled. SAE invites your written comments and suggestions.

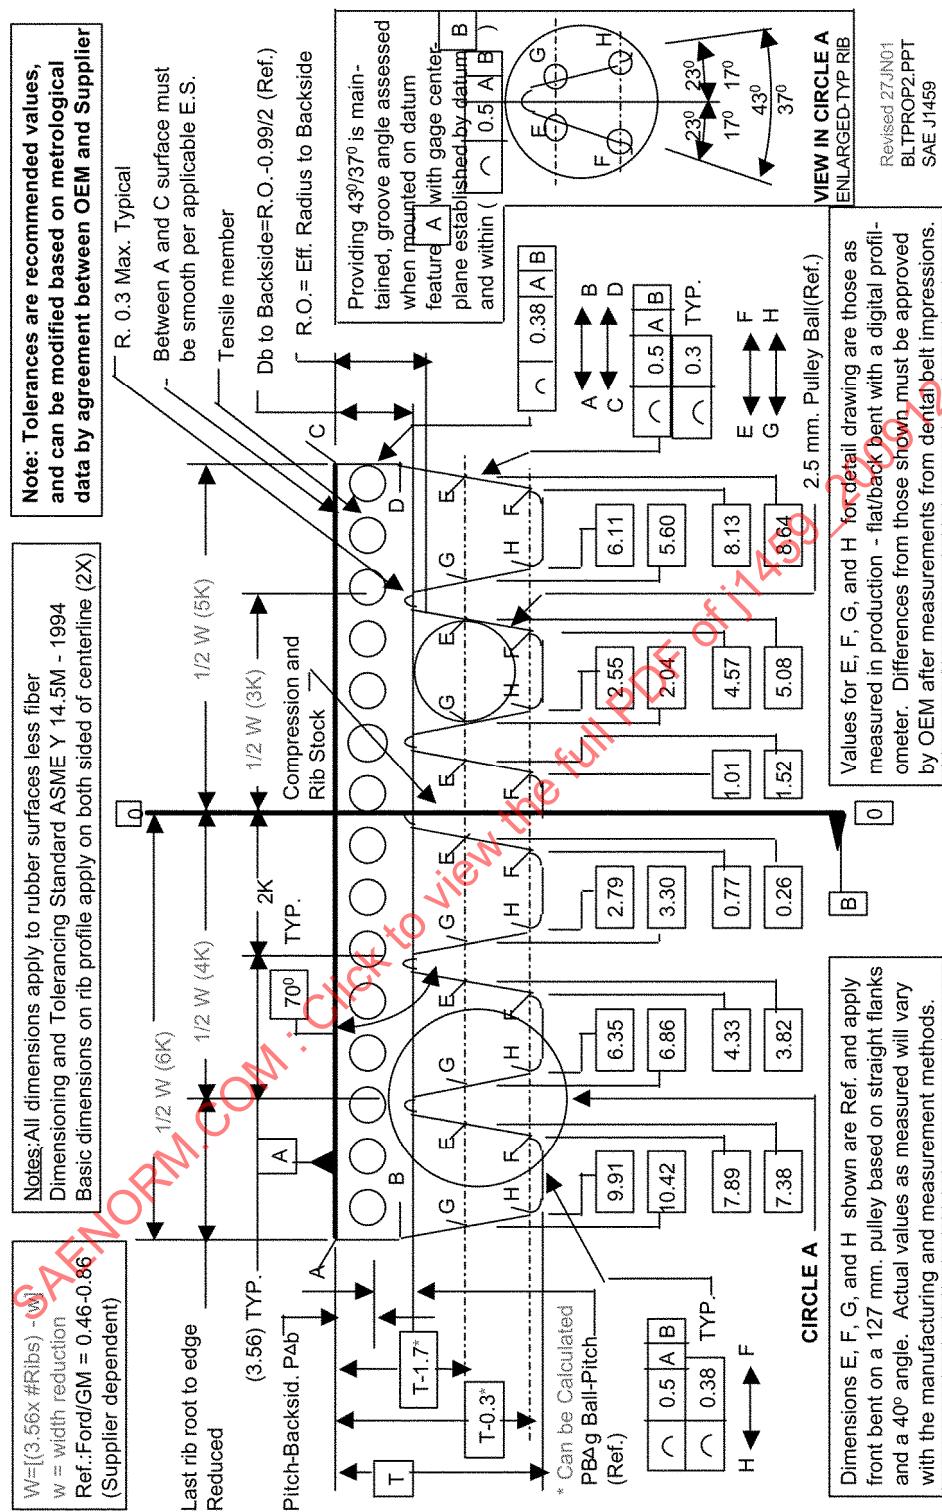

FIGURE 1 - BELT DIMENSIONING TEMPLATE

Notes:

1. This template applies to pulleys with DoB >70mm except where shown
2. All dimensions apply unpainted
3. Dimensioning and tolerancing to ASME Y 14.5M-1994
4. Digital profilometer/vision system required for production metrology
5. Points B & C must be on a line at a greater diameter than the tangent point of the root radii
6. Points D & E must be on a line at a greater diameter less than the tip radii

Y and Z are functions of material thickness and supplier processes; to be defined numerically on the drawing.

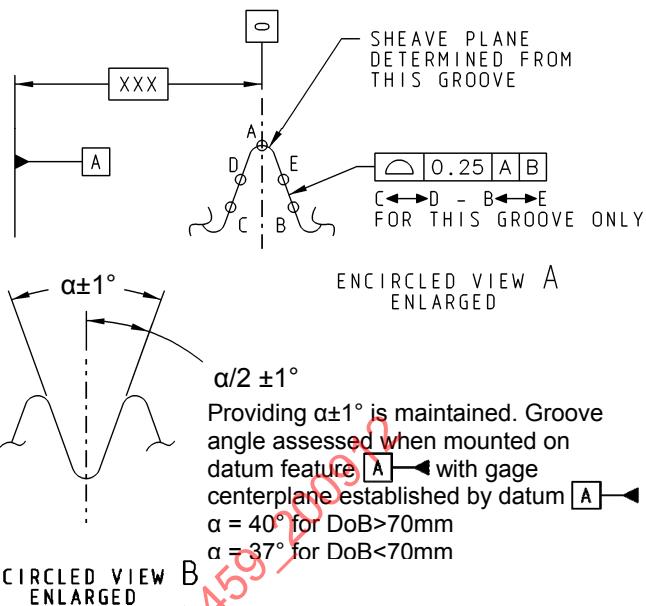

Coating must be smooth and even within AREA A

Tolerances are recommended values, and may be modified based on metrological data by agreement between OEM and supplier

Unless otherwise specified:

Max imbalance = $44/R$ g-cm (R = highest pulley ratio for this pulley)

Stamped surfaces $\triangle 1.6$ A B

Pulleys with DoB <70mm

- 2 x	9.92
- 2 x	7.88
	6.36
- 2 x	4.32
- 2 x	2.79
- 2 x	0.76
-	0.00

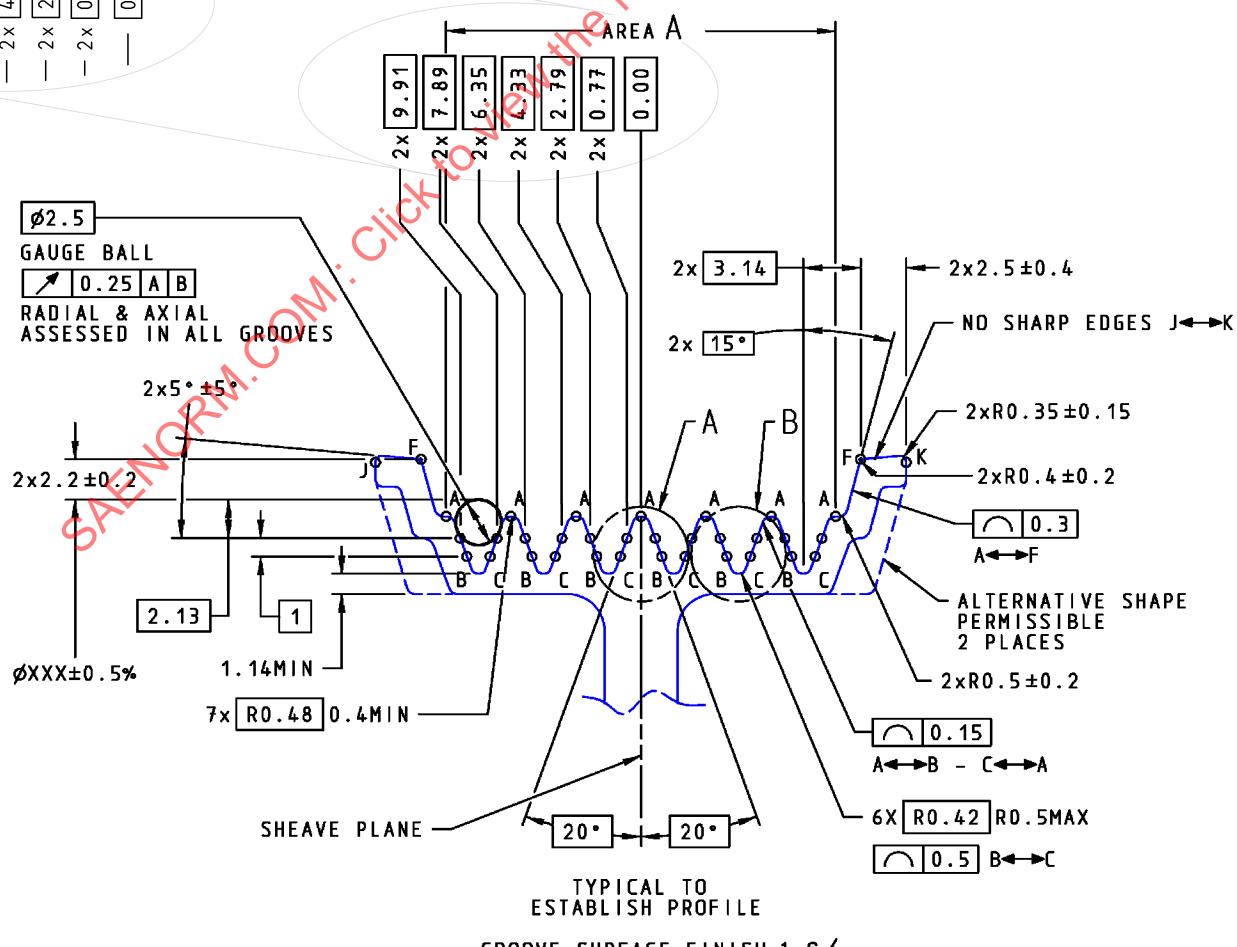

FIGURE 2 - 'SPLIT' PULLEY DIMENSIONING TEMPLATE (6) GROOVE SHOWN (TYPICAL)

Notes:

1. This template applies to pulleys with DoB >70mm except where shown
2. All dimensions apply unpainted
3. Dimensioning and tolerancing to ASME Y 14.5M-1994
4. Digital profilometer/vision system required for production metrology
5. Points B & C must be on a line at a greater diameter than the tangent point of the root radii
6. Points D & E must be on a line at a greater diameter less than the tip radii

Y and Z are functions of material thickness and supplier processes; to be defined numerically on the drawing.

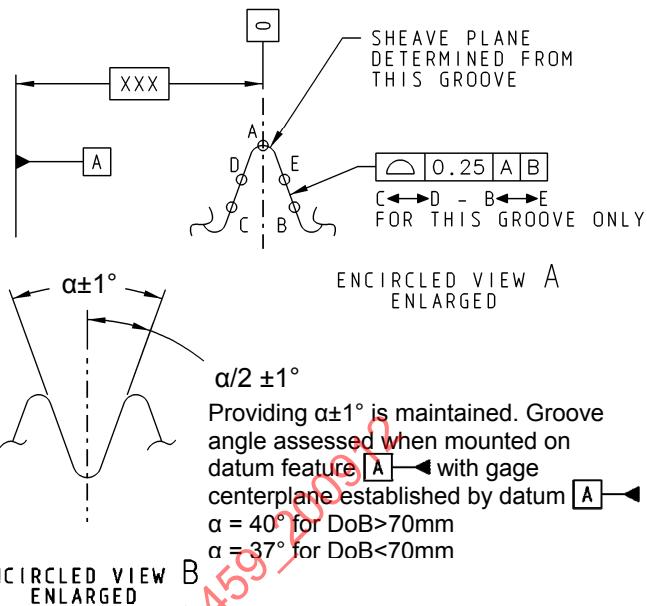

Coating must be smooth and even within AREA A

Tolerances are recommended values, and may be modified based on metrological data by agreement between OEM and supplier

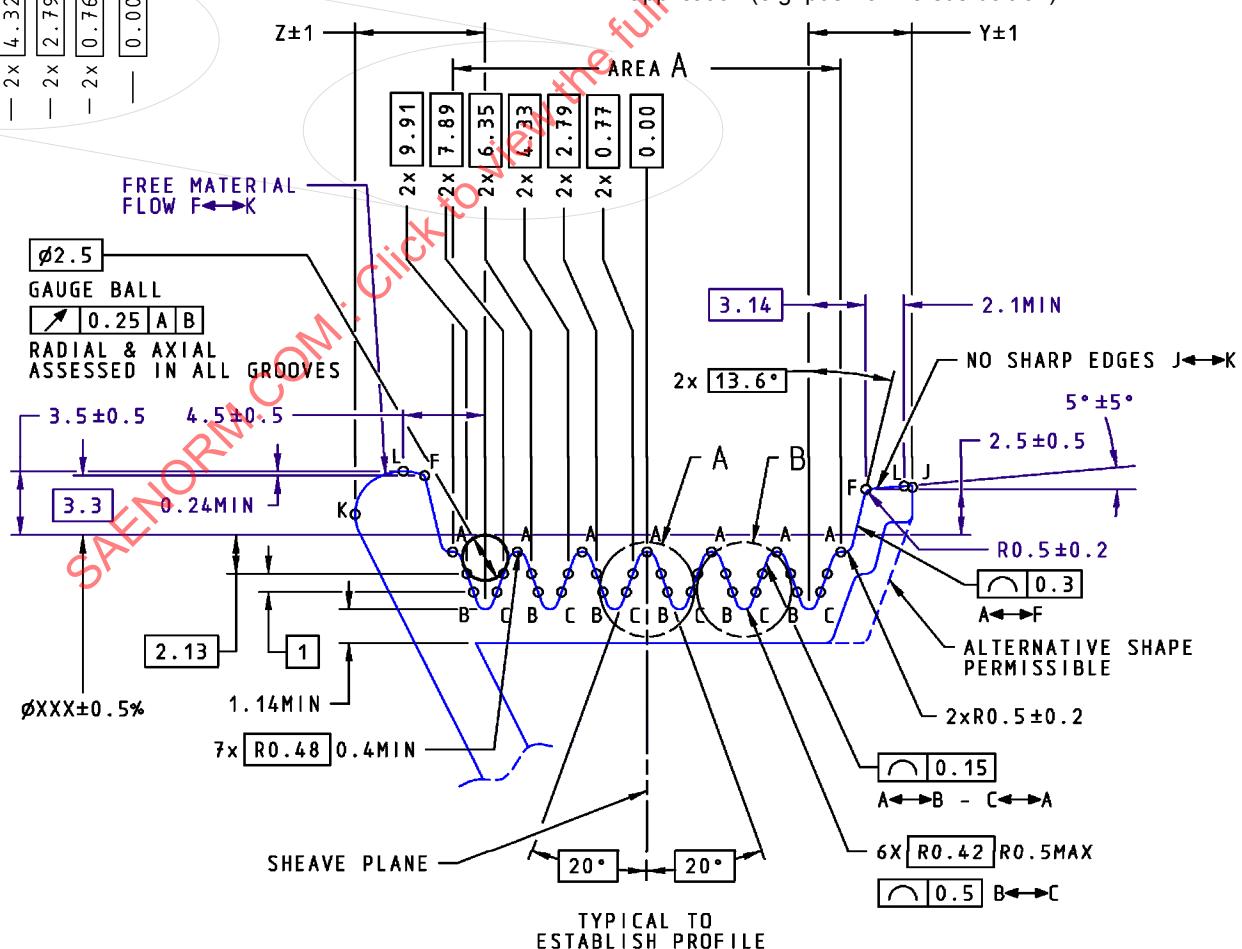

FIGURE 4 - OPTIONAL 'FOLDED' PULLEY DIMENSIONING TEMPLATE (6) GROOVE SHOWN (TYPICAL)

5. MEASUREMENT METHOD

Since the templates in Figures 1 to 4 have profile of a line callouts, it is necessary to capture the entire profile digitally and compare it to the drawing dimensions. This requires a digital profilometer or digital vision system and eliminates the optical comparator as acceptable for metrology. Because of the inherent speed of these devices, the frequency of audit may have to be reduced, depending on the process used in production. If verification of ongoing quality requires more frequent measurement, the audit with the profilometer is still required, while the supplier can use traditional methods to measure additional belts or pulleys to satisfy an internal process control characteristic, if they feel the need.

6. BELT DIMENSION DETERMINATION

The shape of the belt profile changes with bending, either as profiled back bent, if it is not molded, or between manufacture and measurement. The intent of the document is to achieve a precise mating of the belt as bent around a grooved pulley. The 37 degree pulley standard deals with the distortion of the belt around small diameter pulleys. For larger pulleys, the 40 degree belt rib angle is to be defined on a 127 mm pulley as measured in an arch with a dental compound casting, or equivalent. The detail drawing is to show the rib dimensions as measured in production with the digital profilometer (usually flat). These dimensions may be different from those measured in the arch. Once the relationship between the arch and the production measurements due to the rubber distortion is established, the arch dimensions shall not be measured on an ongoing basis, but rather the detail drawing dimensions representing the flat profilometer method.

7. METROLOGICAL ISSUES

In order to facilitate the execution of the programs for digital profilometers to measure both belts and pulleys, it is permissible to calculate the points defined on the flanks of the belt ribs or pulley grooves. This can be done from the line defined by points along the rib/groove flank line between the tangent points of the tip and root radii. Gage R&R improves with increasing distance between the points selected. Precise methodology can be mutually agreed upon between supplier and OEM.

8. V-RIBBED BELT SIZE

Belt size is designated by a standard series of alphanumeric characters. Belts measured on a metric length system are designated by the number of ribs followed by the belt cross-sectional size ("PK" or "PL") and the effective length in millimeters. For example, 6PK1370 signifies a 6-rib "PK" section belt, with an effective length of 1370 mm.

9. MEASUREMENT OF V-RIBBED BELTS

The length of a V-ribbed belt is determined by use of a measuring fixture comprised of two pulleys of equal diameter, a method of applying force, and a means of measuring the center distance between the two pulleys. One of the two pulleys is fixed in position while the other is movable along a graduated scale. Both pulleys are allowed to rotate. The fixture is shown schematically in Figure 5. Grooves of master inspection pulleys shall be machined to dimension tolerances shown in Table 2, treated to resist wear, and checked periodically for wear and damage.
